Session 20: Deadlock Avoidance

#### **Deadlock Avoidance**

Requires that the system has some additional *a prior* information available

- Simplest and most useful model requires that each process declare the *maximum number* of resources of each type that it may need
- The deadlock-avoidance algorithm dynamically examines the resource-allocation state to ensure that there can never be a circular-wait condition
- Resource-allocation state is defined by the number of available and allocated resources, and the maximum demands of the processes

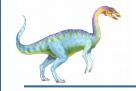

### **Safe State**

- When a process requests an available resource, system must decide if immediate allocation leaves the system in a safe state
- System is in safe state if there exists a sequence  $\langle P_1, P_2, ..., P_n \rangle$  of ALL the processes in the systems such that for each  $P_i$ , the resources that  $P_i$  can still request can be satisfied by currently available resources + resources held by all the  $P_i$ , with j < i
- That is:
  - If  $P_i$  resource needs are not immediately available, then  $P_i$  can wait until all  $P_j$  have finished
  - When  $P_j$  is finished,  $P_i$  can obtain needed resources, execute, return allocated resources, and terminate
  - When  $P_i$  terminates,  $P_{i+1}$  can obtain its needed resources, and so on

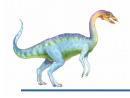

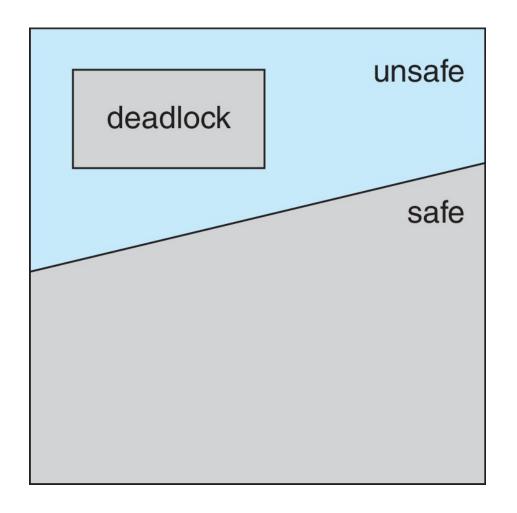

#### **Basic Facts**

- If a system is in safe state ⇒ no deadlocks
- If a system is in unsafe state ⇒ possibility of deadlock
- Avoidance ⇒ ensure that a system will never enter an unsafe state.

## Safe, Unsafe, Deadlock State

### **Avoidance Algorithms**

- Single instance of a resource type
  - Use a resource-allocation graph
- Multiple instances of a resource type
  - Use the Banker's Algorithm

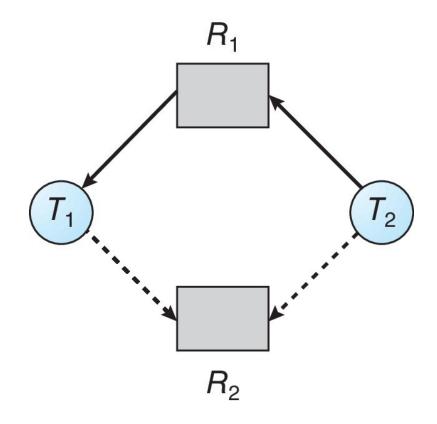

### **Resource-Allocation Graph Scheme**

- Claim edge  $P_i \rightarrow R_j$  indicated that process  $P_j$  may request resource  $R_i$ ; represented by a dashed line
- Claim edge converts to request edge when a process requests a resource
- Request edge converted to an assignment edge when the resource is allocated to the process
- When a resource is released by a process, assignment edge reconverts to a claim edge
- Resources must be claimed a priori in the system

### **Resource-Allocation Graph**

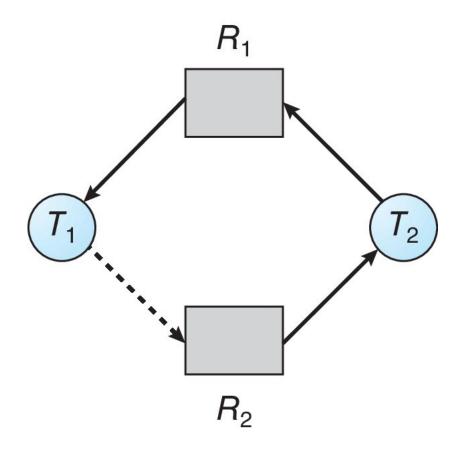

### **Resource-Allocation Graph Algorithm**

- Suppose that process  $P_i$  requests a resource  $R_i$
- The request can be granted only if converting the request edge to an assignment edge does not result in the formation of a cycle in the resource allocation graph

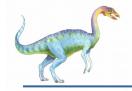

### **Unsafe State In Resource-Allocation Graph**

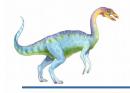

### **Banker's Algorithm**

- Multiple instances of resources
- Each process must a priori claim maximum use
- When a process requests a resource it may have to wait
- When a process gets all its resources it must return them in a finite amount of time

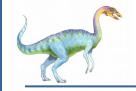

### Data Structures for the Banker's Algorithm

Let n = number of processes, and m = number of resources types.

- Available: Vector of length m. If available [j] = k, there are k instances of resource type  $R_i$  available
- Max:  $n \times m$  matrix. If Max[i,j] = k, then process  $P_i$  may request at most k instances of resource type  $R_i$
- Allocation:  $n \times m$  matrix. If Allocation[i,j] = k then  $P_i$  is currently allocated k instances of  $R_i$
- **Need**:  $n \times m$  matrix. If Need[i,j] = k, then  $P_i$  may need k more instances of  $R_j$  to complete its task

Need [i,j] = Max[i,j] - Allocation [i,j]

### **Safety Algorithm**

 Let Work and Finish be vectors of length m and n, respectively. Initialize:

Work = Available  
Finish 
$$[i]$$
 = false for  $i = 0, 1, ..., n-1$ 

- 2. Find an *i* such that both:
  - (a) Finish [i] = false
  - (b)  $Need_i \leq Work$ If no such i exists, go to step 4
- 3. Work = Work + Allocation; Finish[i] = true go to step 2
- 4. If *Finish* [*i*] == *true* for all *i*, then the system is in a safe state

## **Example of Banker's Algorithm**

■ 5 processes  $P_0$  through  $P_4$ ;

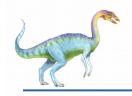

3 resource types:

A (10 instances), B (5instances), and C (7 instances)

Snapshot at time  $T_0$ :

	<u>Allocation</u>	<u>Max</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	0 1 0	753	3 3 2
$P_1$	200	3 2 2	
$P_2$	302	902	
$P_3$	211	222	
$P_{\scriptscriptstyle 4}$	002	4 3 3	

### **Example (Cont.)**

■ The content of the matrix *Need* is defined to be *Max* – *Allocation* 

#### **Need**

ABC

 $P_0$  743

 $P_1$  122

 $P_{2} 600$ 

 $P_3 = 0.11$ 

 $P_{4}$  431

### **Example (Cont.)**

■ The content of the matrix *Need* is defined to be *Max* – *Allocation* 

**Need** 

ABC

 $P_0$  743

 $P_1$  122

 $P_{2} 600$ 

 $P_3 = 0.11$ 

 $P_{4}$  431

The system is in a safe state since the sequence  $\langle P_1, P_3, P_4, P_2, P_0 \rangle$  satisfies safety criteria

## Resource-Request Algorithm for Process $P_i$

 $Request_i$  = request vector for process  $P_i$ . If  $Request_i[j] = k$  then process  $P_i$  wants k instances of resource type  $R_i$ 

- 1. If  $Request_i \leq Need_i$  go to step 2. Otherwise, raise error condition, since process has exceeded its maximum claim
- 2. If  $Request_i \leq Available$ , go to step 3. Otherwise  $P_i$  must wait, since resources are not available
- 3. Pretend to allocate requested resources to  $P_i$  by modifying the state as follows:

Available = Available - Request;; Allocation; = Allocation; + Request;; Need; = Need; - Request;;

- If safe ⇒ the resources are allocated to P<sub>i</sub>
- If unsafe ⇒ P<sub>i</sub> must wait, and the old resource-allocation state is restored

## Example: $P_1$ Request (1,0,2)

Check that Request  $\leq$  Available (that is,  $(1,0,2) \leq (3,3,2) \Rightarrow$  true

<u>Allo</u>	<u>ocation</u>	<u>Need</u>	<u>Available</u>
	ABC	ABC	ABC
$P_{\scriptscriptstyle 0}$	0 1 0	7 4 3	230
$P_1$	302	020	
$P_2$	302	600	
$P_3$	211	0 1 1	
$P_{\scriptscriptstyle 4}$	002	4 3 1	

## Example: $P_1$ Request (1,0,2)

Check that Request  $\leq$  Available (that is,  $(1,0,2) \leq (3,3,2) \Rightarrow$  true

Allo	<u>ocation</u>	<u>Need</u>	<u>Available</u>
	ABC	ABC	ABC
$P_{\scriptscriptstyle 0}$	010	7 4 3	230
$P_1$	302	020	
$P_2$	302	600	
$P_3$	211	0 1 1	
$P_{\scriptscriptstyle 4}$	002	4 3 1	

- Executing safety algorithm shows that sequence  $\langle P_1, P_3, P_4, P_0, P_2 \rangle$  satisfies safety requirement
- Can request for (3,3,0) by  $P_4$  be granted?
- Can request for (0,2,0) by P<sub>0</sub> be granted?

### **Deadlock Detection**

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

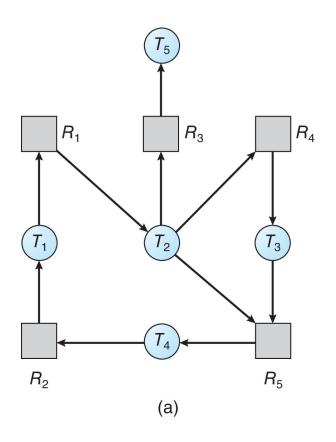

### Single Instance of Each Resource Type

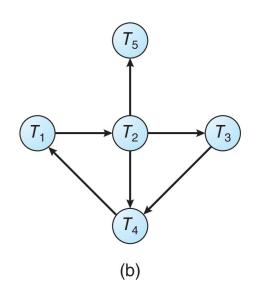

- Maintain wait-for graph
  - Nodes are processes
  - P<sub>i</sub> → P<sub>j</sub> if P<sub>i</sub> is waiting for P<sub>j</sub>
- Periodically invoke an algorithm that searches for a cycle in the graph. If there is a cycle, there exists a deadlock
- An algorithm to detect a cycle in a graph requires an order of  $n^2$  operations, where n is the number of vertices in the graph

#### Resource-Allocation Graph and Wait-for Graph

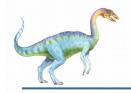

Resource-Allocation Graph

Corresponding wait-for graph

### **Several Instances of a Resource Type**

- Available: A vector of length *m* indicates the number of available resources of each type
- Allocation: An *n* x *m* matrix defines the number of resources of each type currently allocated to each process
- Request: An n x m matrix indicates the current request of each process. If Request [i][j] = k, then process P<sub>i</sub> is requesting k more instances of resource type R<sub>i</sub>.

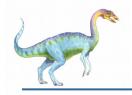

### **Detection Algorithm**

- 1. Let **Work** and **Finish** be vectors of length **m** and **n**, respectively Initialize:
  - (a) Work = Available
  - (b) For i = 1,2, ..., n, if Allocation, ≠ 0, then
    Finish[i] = false; otherwise, Finish[i] = true
- 2. Find an index *i* such that both:
  - (a) Finish[i] == false
  - (b)  $Request_i \leq Work$

If no such *i* exists, go to step 4

### **Detection Algorithm (Cont.)**

- 3. Work = Work + Allocation; Finish[i] = true go to step 2
- 4. If Finish[i] == false, for some i,  $1 \le i \le n$ , then the system is in deadlock state. Moreover, if Finish[i] == false, then  $P_i$  is deadlocked

Algorithm requires an order of  $O(m \times n^2)$  operations to detect whether the system is in deadlocked state

### **Example of Detection Algorithm**

- Five processes  $P_0$  through  $P_4$ ; three resource types A (7 instances), B (2 instances), and C (6 instances)
- Snapshot at time T<sub>0</sub>:

	<u>Allocation</u>	<u>Request</u>	<u>Available</u>
	ABC	ABC	ABC
$P_{\scriptscriptstyle 0}$	0 1 0	000	000
$P_1$	200	202	
$P_2$	303	000	
$P_3$	211	100	
$P_{\scriptscriptstyle 4}$	002	002	

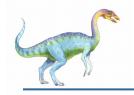

### **Example of Detection Algorithm**

- Five processes  $P_0$  through  $P_4$ ; three resource types A (7 instances), B (2 instances), and C (6 instances)
- Snapshot at time  $T_0$ :

	<u>Allocation</u>	<u>Request</u>	<u>Available</u>
	ABC	ABC	ABC
$P_{o}$	0 1 0	000	000
$P_1$	200	202	
$P_2$	303	000	
$P_3$	211	100	
$P_{\scriptscriptstyle 4}$	002	002	

Sequence  $\langle P_0, P_2, P_3, P_1, P_4 \rangle$  will result in *Finish[i] = true* for all *i* 

### **Example (Cont.)**

P<sub>2</sub> requests an additional instance of type C

#### **Request**

ABC

 $P_0 000$ 

 $P_1$  202

 $P_2 0 0 1$ 

 $P_3$  100

 $P_4 002$ 

State of system?

### **Example (Cont.)**

P<sub>2</sub> requests an additional instance of type C

#### **Request**

ABC

 $P_0 0 0 0$ 

 $P_1$  202

 $P_{2} 001$ 

 $P_3$  100

 $P_4 002$ 

- State of system?
  - Can reclaim resources held by process  $P_0$ , but insufficient resources to fulfill other processes; requests
  - Deadlock exists, consisting of processes P<sub>1</sub>, P<sub>2</sub>, P<sub>3</sub>, and P<sub>4</sub>

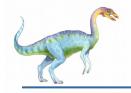

### **Detection-Algorithm Usage**

- When, and how often, to invoke depends on:
  - How often a deadlock is likely to occur?
  - How many processes will need to be rolled back?
    - one for each disjoint cycle
- If detection algorithm is invoked arbitrarily, there may be many cycles in the resource graph and so we would not be able to tell which of the many deadlocked processes "caused" the deadlock.

#### **Recovery from Deadlock: Process Termination**

- Abort all deadlocked processes
- Abort one process at a time until the deadlock cycle is eliminated
- In which order should we choose to abort?
  - 1. Priority of the process
  - How long process has computed, and how much longer to completion
  - Resources the process has used
  - 4. Resources process needs to complete
  - 5. How many processes will need to be terminated
  - 6. Is process interactive or batch?

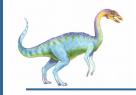

#### **Recovery from Deadlock: Resource Preemption**

- Selecting a victim minimize cost
- Rollback return to some safe state, restart process for that state
- Starvation same process may always be picked as victim, include number of rollback in cost factor

#### **Practice**

سیستمی با 100 واحد حافظه اصلی و 115 واحد حافظه جانبی به شکل زیر به سه پروسس تخصیص داده شده است (هر بردار به ترتیب از چپ به راست مقادیر حافظه اصلی و حافظه جانبی است). پروسس p4 با حداکثر حافظه موردنیاز (95، 60) وارد میشود و مقدار 25 واحد حافظه اصلی و 30 واحد حافظه فرعی درخواست میکند. با به کارگیری الگوریتم بانکداران، مشخص کنید آیا میتوان مقدار درخواست شده را به p4 داد به طوری که مطمئن باشیم در آینده به بن بست نمیخوریم؟

Allocation	Max need	Process
20.10	70,115	P1
40,20	40, 60	P2
15.0	85,60	P3

#### **Practice**

- Compare the circular-wait method (ordering processes) with the various dead-lock avoidance (such as banker) with respect to
  - Run-time overhead
  - System throughput

# **End of Chapter 8**
