Chapter 5 Network Layer: The Control Plane

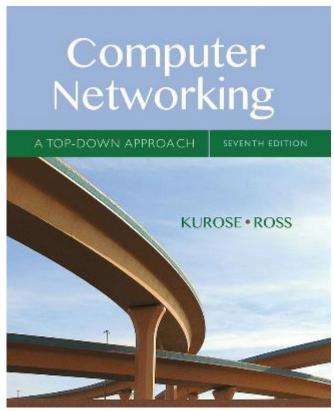

A note on the use of these Powerpoint slides:

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

Computer Networking: A Top Down Approach

7th edition
Jim Kurose, Keith Ross
Pearson/Addison Wesley
April 2016

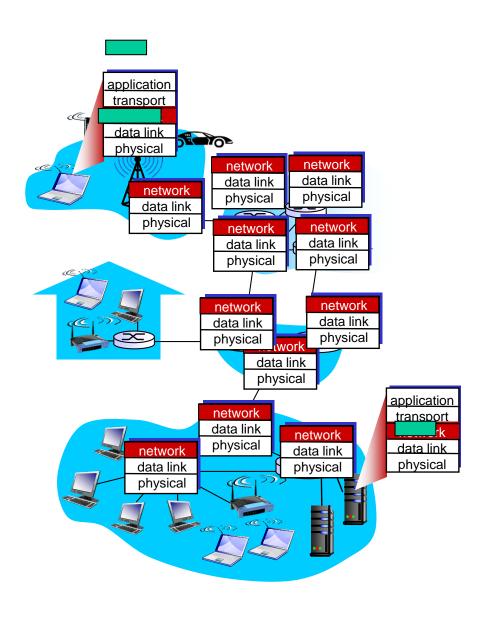

Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.5 The SDN control plane
- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

Network layer

- transport segment from sending to receiving host
- on sending side encapsulates segments into datagrams
- on receiving side, delivers segments to transport layer
- network layer protocols in every host, router
- router examines header fields in all IP datagrams passing through it

Two key network-layer functions

network-layer functions:

- •forwarding: move packets from router's input to appropriate router output
- •routing: determine route taken by packets from source to destination
 - routing algorithms

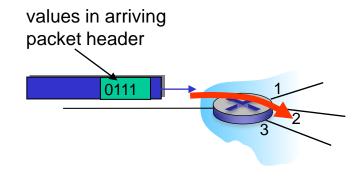

analogy: taking a trip

- forwarding: process of getting through single interchange
- routing: process of planning trip from source to destination

Network layer: data plane, control plane

Data plane

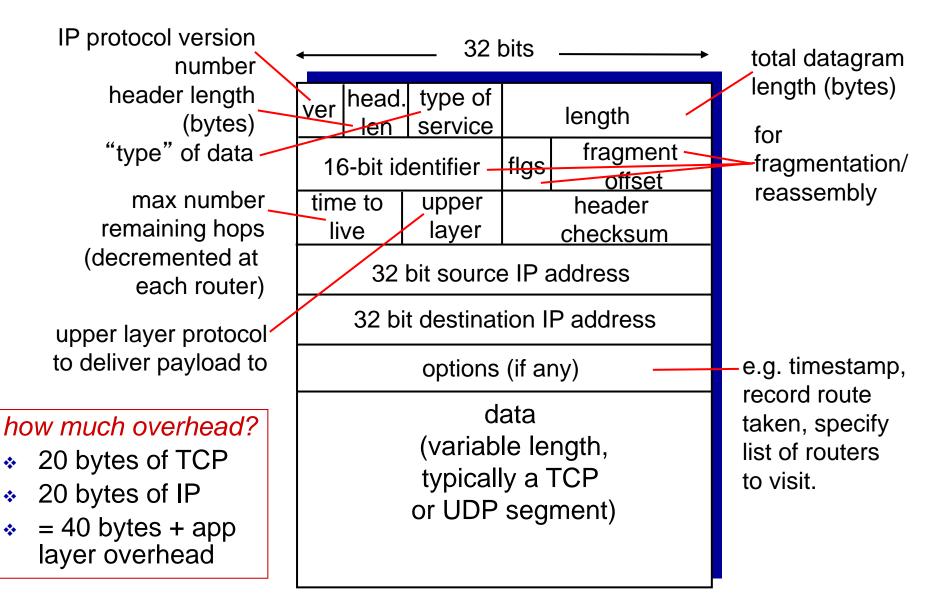

- local, per-router function
- determines how datagram arriving on router input port is forwarded to router output port
- forwarding function

Control plane

- network-wide logic
- determines how datagram is routed among routers along end-end path from source host to destination host

IP datagram format

Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

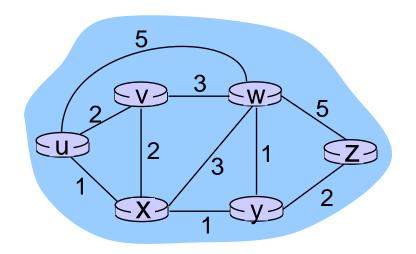

- 5.5 The SDN control plane
- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

Routing protocols

Routing protocol goal: determine "good" paths (equivalently, routes), from sending hosts to receiving host, through network of routers

- path: sequence of routers packets will traverse in going from given initial source host to given final destination host
- "good": least "cost", "fastest", "least congested"
- routing: a "top-10" networking challenge!

Graph abstraction of the network

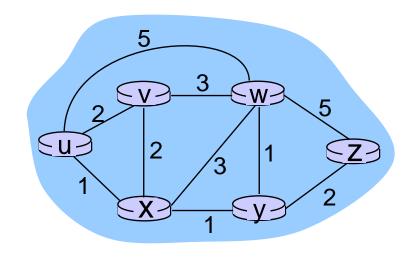

graph: G = (N,E)

 $N = set of routers = \{ u, v, w, x, y, z \}$

 $E = \text{set of links} = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

aside: graph abstraction is useful in other network contexts, e.g., P2P, where *N* is set of peers and *E* is set of TCP connections

Graph abstraction: costs

$$c(x,x') = cost of link (x,x')$$

e.g., $c(w,z) = 5$

cost could always be I, or inversely related to bandwidth, or inversely related to congestion

cost of path
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

key question: what is the least-cost path between u and z? routing algorithm: algorithm that finds that least cost path

Routing algorithm classification

Q: global or decentralized information?

global:

- all routers have complete topology, link cost info
- "link state" algorithms

decentralized:

- router knows physicallyconnected neighbors, link costs to neighbors
- iterative process of computation, exchange of info with neighbors
- "distance vector" algorithms

Q: static or dynamic?

static:

routes change slowly over time

dynamic:

- routes change more quickly
 - periodic update
 - in response to link cost changes

Chapter 5: outline

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.5 The SDN control plane
- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

A link-state routing algorithm

Dijkstra 's algorithm

- net topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- computes least cost paths from one node ('source") to all other nodes
 - gives forwarding table for that node
- iterative: after k
 iterations, know least cost
 path to k destinations

notation:

- C(X,y): link cost from node x to y;
 = ∞ if not direct neighbors
- D(V): current value of cost of path from source to destination v
- p(v): predecessor node along path from source to v
- N': set of nodes whose least cost path definitively known

Dijsktra's algorithm

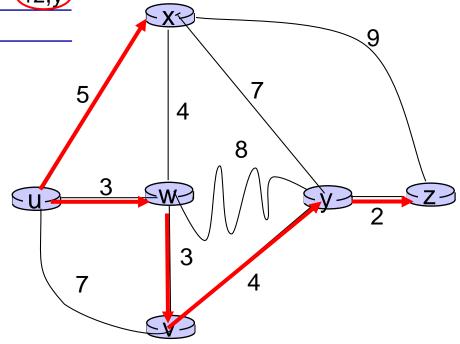

```
Initialization:
  N' = \{u\}
  for all nodes v
    if v adjacent to u
       then D(v) = c(u,v)
    else D(v) = \infty
  Loop
    find w not in N' such that D(w) is a minimum
10 add w to N'
    update D(v) for all v adjacent to w and not in N':
   D(v) = \min(D(v), D(w) + c(w,v))
13 /* new cost to v is either old cost to v or known
   shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

Dijkstra's algorithm: example

		D(v)	D(w)	D(x)	D(y)	D(z)
Ste	o N'	p(v)	p(w)	p(x)	p(y)	p(z)
0	u	7,u	3,u	5,u	∞	∞
1	uw	6,w		(5,u) 11,W	∞
2 3	uwx	6,w			11,W	14,x
3	uwxv				10,V	14,x
4	uwxvy					(12,y)
5	uwxvyz				_	

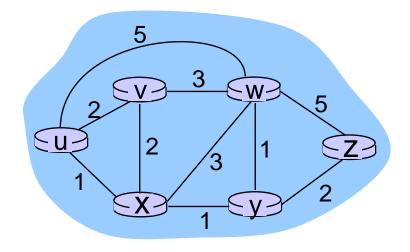

notes:

- construct shortest path tree by tracing predecessor nodes
- ties can exist (can be broken arbitrarily)

Dijkstra's algorithm: another example

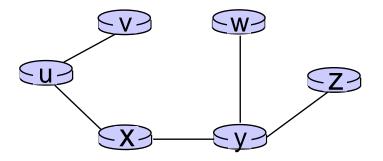

Step	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
0	u	2,u	5,u	1,u	∞	∞
1	ux ←	2,u	4,x		2,x	∞
2	uxy <mark>←</mark>	2, u	3,y			4,y
3	uxyv		3,y			4,y
4	uxyvw ←					4,y
5	uxyvwz ←					

^{*} Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose_ross/interactive/

Dijkstra's algorithm: example (2)

resulting shortest-path tree from u:

resulting forwarding table in u:

destination	link
V	(u,v)
X	(u,x)
У	(u,x)
W	(u,x)
Z	(u,x)
y w z	(u,x) (u,x)

Chapter 5: outline

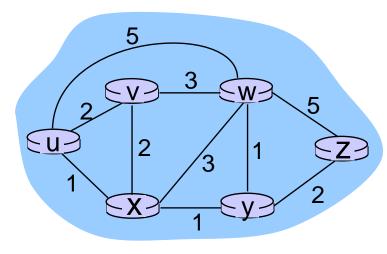

- 5.1 introduction
- 5.2 routing protocols
- link state
- distance vector
- 5.3 intra-AS routing in the Internet: OSPF
- 5.4 routing among the ISPs: BGP

- 5.5 The SDN control plane
- 5.6 ICMP: The Internet Control Message Protocol
- 5.7 Network management and SNMP

Bellman-Ford equation (dynamic programming)

```
let
  d_{y}(y) := cost of least-cost path from x to y
then
  d_{x}(y) = \min_{v} \{c(x,v) + d_{v}(y)\}
                             cost from neighbor v to destination y
                    cost to neighbor v
             min taken over all neighbors v of x
```

Bellman-Ford example

clearly,
$$d_v(z) = 5$$
, $d_x(z) = 3$, $d_w(z) = 3$

B-F equation says:

$$d_{u}(z) = \min \{ c(u,v) + d_{v}(z), \\ c(u,x) + d_{x}(z), \\ c(u,w) + d_{w}(z) \}$$

$$= \min \{ 2 + 5, \\ 1 + 3, \\ 5 + 3 \} = 4$$

node achieving minimum is next hop in shortest path, used in forwarding table

- $D_x(y)$ = estimate of least cost from x to y
 - x maintains distance vector $\mathbf{D}_{x} = [\mathbf{D}_{x}(y): y \in \mathbb{N}]$
- node x:
 - knows cost to each neighbor v: c(x,v)
 - maintains its neighbors' distance vectors. For each neighbor v, x maintains

$$\mathbf{D}_{v} = [D_{v}(y): y \in \mathbb{N}]$$

key idea:

- from time-to-time, each node sends its own distance vector estimate to neighbors
- when x receives new DV estimate from neighbor, it updates its own DV using B-F equation:

$$D_x(y) \leftarrow \min_{v} \{c(x,v) + D_v(y)\}$$
 for each node $y \in N$

* under minor, natural conditions, the estimate $D_x(y)$ converge to the actual least cost $d_x(y)$

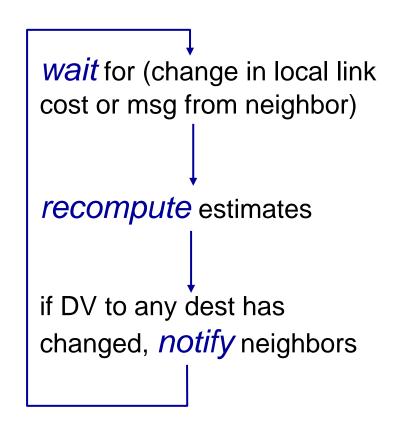

iterative, asynchronous: each local iteration caused by:

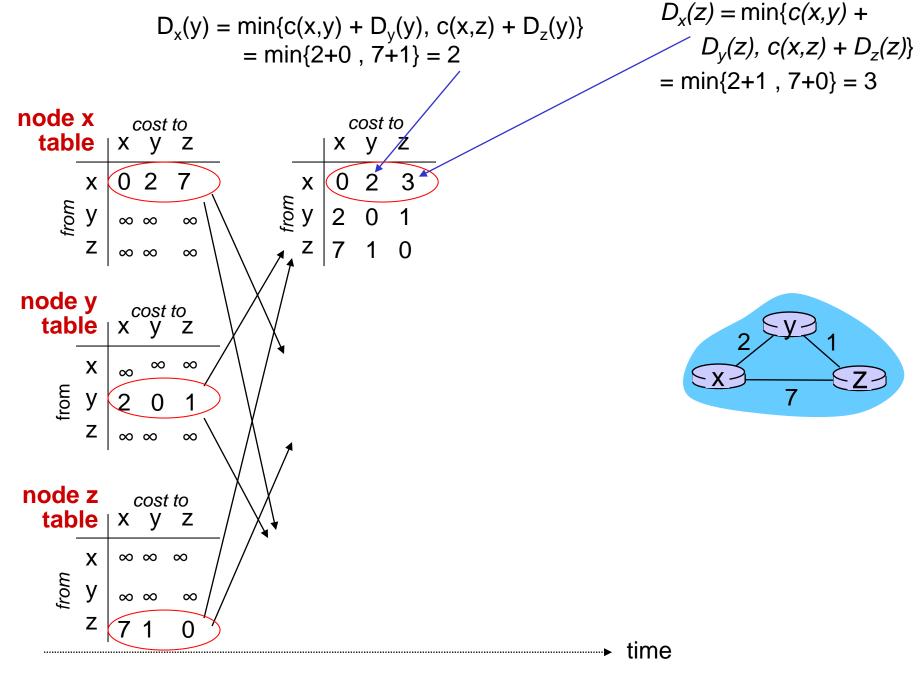

- local link cost change
- DV update message from neighbor

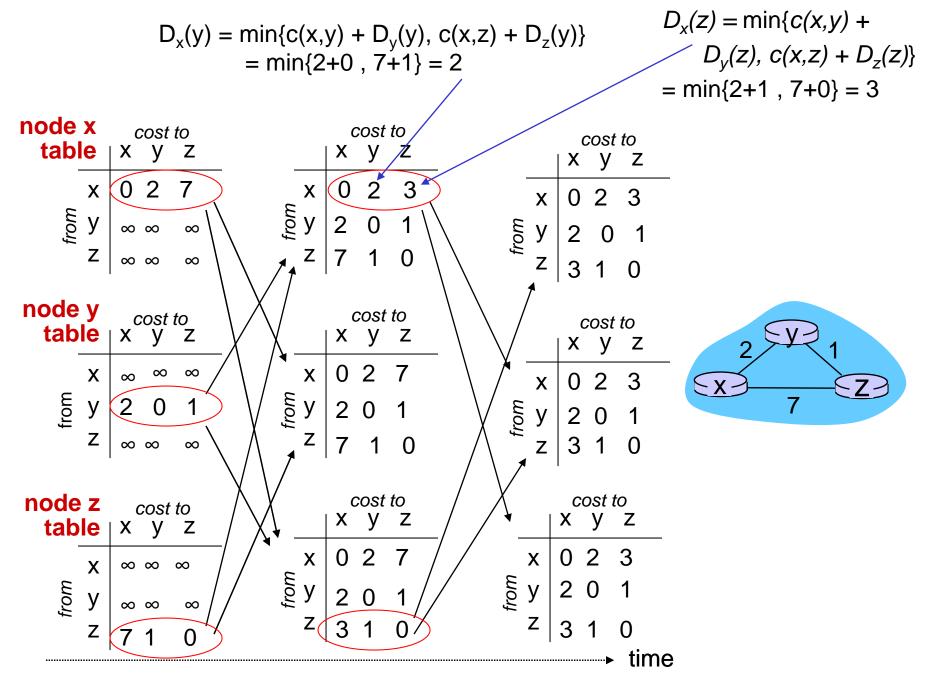

distributed:

- each node notifies neighbors only when its DV changes
 - neighbors then notify their neighbors if necessary

each node:

Comparison of LS and DV algorithms

message complexity

- LS: with n nodes, E links, O(nE) msgs sent
- DV: exchange between neighbors only
 - convergence time varies

speed of convergence

- LS: O(n²) algorithm requires
 O(nE) msgs
 - may have oscillations
- DV: convergence time varies
 - may be routing loops
 - count-to-infinity problem

robustness: what happens if router malfunctions?

LS:

- node can advertise incorrect link cost
- each node computes only its own table

DV:

- DV node can advertise incorrect path cost
- each node's table used by others
 - error propagate through network
